

Cursor Prompt – Bit Reel Handling Enhancement (Reel Inventory ERP)

Context:

You are extending an already working Reel Inventory ERP built using the MERN stack.

All existing features (login, dashboard, inward, usage, calculations) are functioning correctly.

Do NOT refactor or modify existing logic outside this scope.

Definition:

A Bit Reel is the leftover partial reel weight after daily production usage.

It must be tracked, carried forward, and included in stock calculations.

UI Requirement:

Add a numeric input field labeled "Bit Reel (KG)" on the transaction page.

Default value: 0

Allow only positive numbers.

Place below the Usage input.

Minimal UI change only.

Database Update:

Extend the existing ReelTransactions schema by adding:

bitReelKg (Number, default 0)

Transaction Validation Rules:

usageKg + bitReelKg must not exceed available stock.

bitReelKg must be ≥ 0 .

Stock Calculation Logic:

Closing Stock =

Opening Stock

+ Today's Inward

- Today's Usage

+ Bit Reel

Carry Forward Logic:

Bit reel weight must automatically carry forward to the next day.

It must be included in the next day's opening stock.

Operator should not manually re-enter bit reel again.

Dashboard Update:

No new column required.

Closing stock must already reflect bit reel weight.

API Update:

Extend existing transaction API to accept and store bitReelKg.

Use it in calculation logic.

Do not change routes or break existing APIs.

Restrictions:

Do not refactor unrelated code.

Do not alter authentication.

Do not create new collections.

Do not simplify ERP logic.

Final Goal:

Seamlessly integrate Bit Reel handling without breaking existing functionality.
